SEMINAR SUMMARY: APRIL 21, 2026 - BRENT CODY CONNECTIONS BETWEEN GRAPH THEORY AND MUSIC

ROB TOMPKINS

We start with an introduction to modular synthesizers. But we are quickly confronted with a problem about maximal evenness, presenting a 12-cycle C_{12}, we are curious about the maximal placing of 5 onsets over the cycle of 12. We try to space the onsets alternatively at first, and we get a section of three uncovered vertices in the cycle. We do a little fiddling, and we end up with the repeating pattern of the black-keys on a piano over the white keys on the piano. The set $J^0_{12,5} = \{0, 2, 4, 7, 9\}$ is the maximally even subset of C_{12}.

So naturally we ask, what does it mean to be maximally even? We come up with the following definition

Definition 1. (Clough, Douthett, 1991) Let $d(u, v)$ represent the distance from vertex u to vertex v of shortest length where $u, v \in C_n$, with C_n being the cycle on n-vertices. We call a set of vertices $\{a_0, a_1, \ldots, a_{m-1}\} \subseteq C_n$ *maximally even* if whenever there is $1 \leq k \leq \lfloor m/2 \rfloor$, we have

$$d(a_i, a_{i+k}) \in \left\{ \left\lfloor \frac{nk}{m} \right\rfloor, \left\lceil \frac{nk}{m} \right\rceil \right\}$$
